

1 **Multimodal Methods for Analyzing Learning and Training Environments: A**
2 **Systematic Literature Review**
3

4 CLAYTON COHN, Vanderbilt University, USA
5 EDUARDO DAVALOS, Vanderbilt University, USA
6 CALEB VATRAL, Tennessee State University, USA
7 JOYCE HORN FONTELES, Vanderbilt University, USA
8 HANCHEN DAVID WANG, Vanderbilt University, USA
9 AUSTIN COURSEY, Vanderbilt University, USA
10 SURYA RAYALA, Vanderbilt University, USA
11 ASHWIN T S, Vanderbilt University, USA
12 MEIYI MA, Vanderbilt University, USA
13 GAUTAM BISWAS, Vanderbilt University, USA

14
15 This document serves as the appendix to our literature review on multimodal methods applied to learning and training environments.
16 It provides supplementary material not included in the main manuscript, including a comprehensive table of all publications in the
17 review corpus, a detailed description of the literature search and screening procedures, discussion of the limitations of the review, and
18 extended results.

19
20 CCS Concepts: • Applied computing → Education; Computer-assisted instruction; Interactive learning environments;
21 Collaborative learning; E-learning; Computer-managed instruction;

22
23 Additional Key Words and Phrases: multimodal data, data analytics, learning analytics, multimodal learning analytics, mmla, learning
24 environments, training environments

25 **ACM Reference Format:**

Table 1. Each of the 122 works in our corpus.

422 B Corpus Distillation Procedure

423 This appendix contains a detailed account of the steps we took to gather relevant works for our literature review and
 424 how we distilled the initial search results to the 73 and 49 papers for Corpora A and B, respectively.
 425

426 B.1 Literature Search

427 The literature search for both corpora was based on search strings collaboratively defined and agreed upon by the
 428 authors as representative of the target research space. Rather than conducting queries manually, we used SerpAPI [165],
 429 a third-party Google Scholar scraping API selected for its ability to return organic search results—unlike alternatives
 430 such as scholarly [35] and gscholar [194], whose outputs differ from browser-based queries.
 431

432 For Corpus A, we queried Google Scholar via API for papers published between January 2017 and October 2022. The
 433 2017 cutoff was chosen to capture developments from the past five years while excluding earlier foundational work,
 434 which is discussed in Sections 1 and 2 of the main manuscript but not included in the corpus. The Corpus B search
 435 was conducted in August 2025 and backdated to begin in November 2022, covering the period following the release of
 436 ChatGPT. We timed the search to follow major conference publication cycles (LAK, AIED, EDM, and L@S) to ensure
 437 comprehensive coverage.
 438

439 The Corpus A search included 14 distinct phrases, each queried three times using variations of the word *multimodal*
 440 (*multimodal*, *multi-modal*, and *multi modal*) as prefixes.¹ For Corpus B, we used 12 updated queries reflecting recent
 441 developments in GenAI and LLMs, employing only the standard spelling of *multimodal* after confirming that alternative
 442 spellings had no impact on results. We also omitted broad terms such as “multimodal survey” and “multimodal literature
 443 review,” which surfaced naturally in other targeted searches. The complete list of search phrases is shown in Table 2.
 444

462	tutoring systems	462	
463	xai	463	

464 (a) Corpus A Search Terms

465 (b) Corpus B Search Terms

466 For each search string, we collected the top five pages (100 publications) returned by Google Scholar. This top-5
 467 cutoff was imposed for practical and financial reasons related to the subsequent construction of a citation graph (see
 468

469 ¹The term “xai” was included to identify works on explainable AI in learning and training contexts; however, no relevant results were returned during the
 470 initial search.

⁴⁷⁴ Appendix B.2.1). SerpAPI limits citation queries to 20 citations per API call, requiring multiple calls for highly cited
⁴⁷⁵ papers (e.g., five calls for a paper with 100 citations). Without a cutoff, the number of API calls would become intractable.
⁴⁷⁶

⁴⁷⁷ The initial search yielded 4,200 papers for Corpus A (14 search terms \times 3 multimodal spelling variants \times 100 results)
⁴⁷⁸ and 1,200 papers for Corpus B (12 search terms \times 1 multimodal spelling variant). The full corpus reduction procedure is
⁴⁷⁹ detailed in Table 3 and discussed in the following subappendices. Each step is referenced using the corresponding Step
⁴⁸⁰ ID in Table 3.

Step	Procedure	Removed A	Remain A	Removed B	Remain B
0	Literature search	0	4200	0	1200
1	Remove duplicates	2079	2121	355	845
2	Remove non-English	1	2120	0	845
3	Remove degree-0 nodes/disconnected components	589	1531	33	812
4	Iteratively remove degree-1 nodes	468	1063	253	559
5	Title reads	675	388	305	254
6	Abstract reads	261	127	110	144
7	Full paper reads	54	<u>73</u>	95	<u>49</u>

Table 3. Corpus reduction procedure.

⁴⁹⁴ We removed 2,079 duplicates from Corpus A and 355 from Corpus B by hashing paper titles (Table 3, Step 1), retaining
⁴⁹⁵ the official published version when multiple copies existed. We then excluded one non-English paper from Corpus A
⁴⁹⁶ (Step 2), identified using spaCy FastLang [191] and verified through manual inspection. After these steps, the combined
⁴⁹⁷ search yielded 2,120 unique English-language papers for Corpus A and 855 for Corpus B.

B.2 Study Selection

To reduce the corpora to a reviewable set, we applied both quantitative and qualitative methods. First, we performed citation graph pruning (CGP) to distill the corpus algorithmically (Appendix B.2.1). This was followed by qualitative screening, detailed in Appendix B.2.2.

⁵⁰³ **B.2.1 Citation Graph Pruning (Quantitative Corpus Reduction).** For visualization, analysis, and corpus distillation, we
⁵⁰⁴ used NetworkX [82] to construct a directed citation graph for all remaining papers. Each node corresponds to a paper
⁵⁰⁵ identified by its Google Scholar UUID, and each directed edge denotes a citation from one corpus paper to another.
⁵⁰⁶ Following SerpAPI’s “cited by” results, only inbound citation queries were required; citations from papers outside the
⁵⁰⁷ list of remaining papers were ignored.

We first removed all 0-degree nodes and disconnected components (Step 3)—papers that neither cited nor were cited
⁵¹¹ by any other paper in the corpus and components with no edges to or from the primary (i.e., largest by number of nodes)
⁵¹² component. Because incoming and outgoing citations jointly determine degree, this approach balances early papers
⁵¹³ (with few outgoing edges) and recent papers (with few incoming edges). Step 3 removed 589 papers from Corpus A and
⁵¹⁴ 33 from Corpus B, resulting in connected citation graphs of 1,531 and 812 papers, respectively.

We then applied iterative degree-1 pruning (Step 4), removing nodes with only one citation edge and repeating the
⁵¹⁸ process until none remained. Corpus A required four iterations, removing 468 papers and yielding 1,063; Corpus B
⁵¹⁹ required two, removing 253 and yielding 559. This approach allowed us to eliminate loosely connected papers unlikely
⁵²⁰ Manuscript submitted to ACM

526 to be central to the field. Given that multimodal learning and training research spans multiple disciplines (e.g., computer
 527 science, education, psychology), the authors agreed that papers with minimal citation connectivity were unlikely to
 528 meet the scope of this review. The CGP algorithm is detailed in Algorithm 1.
 529

Algorithm 1 Citation Graph Pruning Algorithm

```

Require: Acyclic directed graph  $G = (V, E)$ 
1: procedure DEGREE TRIMMING( $G, n$ )
2:    $S, D \leftarrow \{\}, \{\}$ 
3:   for all  $v \in V$  do
4:     if  $\deg(v) \leq n$  then  $S = S \cup \{v\}$ 
5:   for all  $v \in S$  do
6:     for all  $e \in E$  do
7:       if  $v \in e \wedge e \notin D$  then  $D = D \cup \{e\}$ 
8:   return  $(V \setminus S, E \setminus D)$ 
9: procedure SUBCONNECTED GRAPH TRIMMING( $G$ )
10:   $[S_1, S_2, S_3, \dots, S_n] = \text{ConnectedComponent}(G)$ , where each  $S_i = (V_i, E_i)$ 
11:   $j = \arg \max\{|V_1|, |V_2|, |V_3|, \dots, |V_n|\}$ 
12:  return  $(V_j, E_j)$ 
13: procedure ITERATIVE TRIMMING( $G$ )
14:  while True do
15:     $G' = \text{DegreeTrimming}(G, 1)$ , where  $G' = (V', E')$ 
16:    if  $|V| == |V'|$  then
17:      break
18:    return  $(V', E')$ 
19:  $G' = \text{DegreeTrimming}(G, 0)$                                  $\triangleright$  Remove 0-deg vertices
20:  $G' = \text{SubconnectedGraphTrimming}(G')$                    $\triangleright$  Keep largest connected subgraph
21:  $G' = \text{IterativeTrimming}(G')$                              $\triangleright$  Iteratively remove 1-deg vertices until equilibrium
22: return  $G'$ 

```

557 At this point, we concluded the quantitative pruning procedure. The resulting citation graphs served as the basis for
 558 subsequent qualitative screening.

560 **B.2.2 Quality Control (Qualitative Corpus Reduction).** Following quantitative pruning, qualitative screening further
 561 reduced each corpus according to the procedures summarized in Table 3. For Corpus A, the remaining 1,063 papers
 562 proceeded through title, abstract, and full-paper review. For Corpus B, due to time constraints, we used an LLM-as-a-Judge
 563 workflow [214] for title, abstract, and full-paper decisions, with human verification on the final distilled set.

566 **Title Screening.** For Corpus A, four reviewers independently evaluated all 1,063 titles for relevance to multimodal
 567 learning or training. Inclusion and exclusion were determined by majority vote, with ties resolved by a fifth reviewer.
 568 This resulted in 388 retained titles and 675 exclusions (Table 3, Step 5 for A). For Corpus B, title decisions were
 569 made jointly by GPT-4o and Gemini 2.5; agreement between both models determined inclusion or exclusion, and
 570 disagreements were adjudicated by a human reviewer. Title screening retained 254 papers, excluding 305 (Step 5 for B).

573 **Abstract Screening.** For abstract screening (Step 6), each Corpus A abstract was reviewed by two reviewers using the
 574 exclusion criteria in Table 4. Papers without unanimous reviewer agreement underwent a second round of review using
 575 majority voting. This yielded 127 retained abstracts and 261 exclusions. For Corpus B, both LLM judges independently
 576

evaluated all abstracts under the same criteria. Agreement resulted in automatic inclusion or exclusion; disagreements were resolved by a human reviewer. A total of 144 abstracts were retained.

Full-Paper Screening. Full-paper review followed the same exclusion framework with two additional criteria introduced during reading (Table 5). For Corpus A, 127 papers were divided among five reviewers. Papers were labeled “immediate accept,” “immediate exclude,” or “borderline.” Exclusion required unanimous agreement across all reviewers. After this stage, 73 papers remained (Table 3, Step 7). For Corpus B, both LLM judges evaluated all 144 papers end-to-end using the cumulative exclusion criteria, selecting 79 papers (including a human tie-breaker) for inclusion. Two human reviewers then manually reviewed and discussed each of these papers to assess their alignment with the scope of this review. Based on consensus coding [34], 30 papers were excluded, resulting in a final set of 49 papers. This human-in-the-loop validation ensured that all retained papers met the inclusion criteria and were within the scope of this literature review.

Across both corpora, qualitative screening ensured that only papers presenting original multimodal methods applied to learning or training environments advanced to the final analysis set: 73 papers for Corpus A and 49 for Corpus B.

B.3 Feature Extraction

Feature extraction was performed after the full paper review stages (Table 3, Steps 7) and was conducted manually by two human reviewers for all 73 papers in Corpus A and all 49 papers in Corpus B. Extracted features included identifying information (e.g., title, author, year) and methodological descriptors (e.g., data collection media, modalities, fusion strategies, and analysis methods). Table 6 lists the initial feature set.

To ensure consistency, feature categories were initially discretized through inductive coding [190]. Four reviewers each coded a portion of the papers in Corpus A to define discrete feature sets. For example, “video camera,” “webcam,” and “Kinect” were consolidated under the medium “video.” Reviewers then re-extracted features into these discrete sets. The resulting circumscribing features are shown in Table 7 (Cohen’s $\kappa = 0.87$).

A second Corpus A feature extraction round gathered additional features supporting later analysis. These circumscribing features—environment setting, domain, participant interaction structure, didactic nature, level of instruction or training, analysis approach, and analysis results—are listed in Table 8. All were discretized except analysis results, which were recorded in free form for thematic analysis [20]. As with the first round, feature extraction for the second

-
1. Paper does not involve a learning or training environment
 2. Environment is VR-only
 3. No multimodal data are analyzed
 4. No multimodal analysis methods are applied
 5. Paper is not original applied research
-

Table 4. Exclusion criteria for abstract screening.

Feature	Description
UUID	Universally unique identifier on Google Scholar
Title	Publication title
First Author	Publication's first author
Year	Year first publicly available
Environment Type	Type of environment analyzed
Data Collection Media	Types of data collected
Modalities	Modalities used during analysis
Analysis Methods	Methods applied in the analysis
Fusion Type	Data fusion strategies used
Publication Source	Journal, conference, workshop, etc.

Table 6. Initial features extracted from each paper.

Feature	Feature Set
Environment Type	learning, training
Data Collection Media	video, audio, screen recording, eye tracking, logs, physiological sensor, interview, survey, participant produced artifacts, researcher produced artifacts, motion, text
Modalities	affect, pose, gesture, activity, prosodic speech, transcribed speech, qualitative observation, logs, gaze, interview notes, survey, pulse, EDA, body temperature, blood pressure, EEG, fatigue, EMG, participant artifacts, researcher artifacts, audio spectrogram, text, pixel
Analysis Methods	classification, regression, clustering, qualitative, statistical methods, network analysis, pattern extraction
Fusion Type	early, mid, late, hybrid, other

Table 7. First set of circumscribing features and their feature sets.

feature set of Corpus A involved independent coding by two reviewers followed by consensus. For this round, Cohen's κ prior to consensus was 0.71.

Once the feature sets were finalized, this process was applied to Corpus B using two human reviewers for consensus coding (Cohen's $\kappa = 0.68$ prior to consensus). For each corpus, final feature sets represent agreement between the reviewers who coded each paper.

C Extended Results

Through our inductive analysis of the review corpus, we developed a theoretical framework that captures the core components of multimodal learning and training pipelines along with their interrelations. As illustrated in Figure 1, the framework decomposes the MMLA process into four primary, sequential component processes: (1) the learning or training environment from which student data are collected through sensors, (2) multimodal data and the modalities derived from them, (3) learning analytics for making sense of that data, and (4) feedback for stakeholders like students,

Feature	Feature Set
Environment Setting	physical, virtual, blended, unspecified
Domain of Study	STEM, humanities, psychomotor skills, other, unspecified
Participant Interaction Structure	individual, multi-person
Didactic Nature	instructional, training, informal, unspecified
Level of Instruction or Training	K-12, university, professional development, unspecified
Analysis Approach	model-free, model-based
Feedback	direct, indirect

Table 8. Second set of circumscribing features and their feature sets.

teachers, and researchers. We provide an overview of each component below, followed by subsections presenting taxonomies and findings corresponding to each.

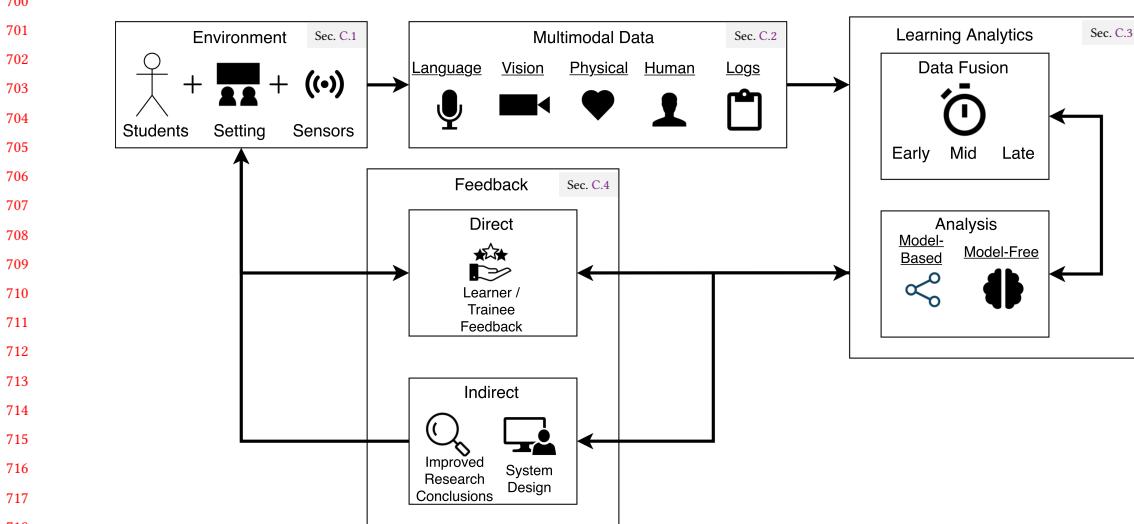

Fig. 1. Multimodal Learning and Training Environments Literature Review Framework

In the following subsections, each framework component is presented via: (1) its significance within the context of multimodal learning and training methodology; (2) a taxonomy derived from data extracted from the reviewed studies; (3) relevant findings, including a comparison of methodologies from the pre-LLM and post-LLM eras and their challenges; and (4) examples of how each component is put into practice.

C.1 Environments

Our paper explores a spectrum of environments on a learning-training continuum (Figure 2). The environments span from traditional classrooms to online courses and are categorized along two dimensions: the learning-training axis [126, 140, 151, 196] and the physical-virtual space continuum [22, 50, 153]. Systems such as nurse training simulations

Manuscript submitted to ACM

734 with manikins and embodied learning environments used in K-12 education (where students actively move around
 735 the classroom as part of the learning experience [74]) combine physical and virtual elements and are referred to as
 736 *mixed-reality* environments [97, 98].
 737

738 Multimodal methods in learning environments aim to
 739 enhance educational outcomes by analyzing student en-
 740 gagement and learning patterns. In contrast, training en-
 741 vironments focus on skill acquisition and task proficiency,
 742 serving individuals from personal development to profes-
 743 sional enhancement across fields such as healthcare [60],
 744 athletics [126], the workplace [3, 97], and the military
 745 [84]. These settings range from fully virtual simulations
 746 to physical training drills, with mixed reality bridging
 747 the gap. MMLA objectives differ between learning and
 748 training, requiring context-specific strategies. While the
 749 distinction between learning and training can be am-
 750 biguous, as seen in game-based platforms [123, 201], our
 751 review spans this spectrum. We employ a fuzzy qualita-
 752 tive categorization to place each study on this continuum,
 753 acknowledging the approach's complexity and utility for analyzing MMLA research sub-communities.
 754

755 In the following subsections, we present findings for the three components specified in our framework for environ-
 756 ment: **learners/trainees** (students), **setting**, and **data collection media** (sensors).
 757

758 *C.1.1 Learners/Trainees (“Students” in Figure 1).* Learners and trainees are central to the design, deployment, and
 759 evaluation of multimodal learning and training analytics systems. The identity of the participants, the subjects they study,
 760 their methods of interaction, and the instructional settings in which they are situated influence the multimodal data that
 761 can be collected, the models that can be developed, and how the resulting analytics should be implemented. Therefore,
 762 clearly defining these learner characteristics is essential to our framework and provides a consistent perspective for
 763 understanding how studies are situated within authentic learning and training environments.

764 Across both Corpora A and B, we describe the learner context along four dimensions: (1) **domain of study**, (2)
 765 **participant interaction structure**, (3) **didactic nature of the environment**, and (4) **level of instruction or**
 766 **training**. The same taxonomy is applied throughout, and individual studies can receive multiple labels along each
 767 dimension.
 768

769 *Domain of Study.* Our corpus revealed three primary domains of study. **STEM+C** includes Science, Technology,
 770 Engineering, Mathematics, and Computing, as well as healthcare and medicine [7, 71, 178]. **Humanities** spans literature,
 771 debate, oral presentation, and writing [151, 157, 162]. **Psychomotor Skills** refers to domains emphasizing motor
 772 coordination, such as CPR training [131], woodworking [29], and video games like PAC-MAN [78].
 773

774 Both Corpora A and B primarily focused on STEM+C learning (A: 55/73, 75%; B: 37/49, 76%), covering topics from
 775 programming [25] to nursing [70] to geometry and chemistry [28]. Psychomotor skills were less represented (A: 5/73,
 776 7%; B: 1/49, 2%). Corpus B showed increased attention to the humanities (A: 11/73, 15%; B: 13/49, 27%), where LLMs
 777 enabled support for open-ended tasks such as multimodal composition and essay writing [112].
 778

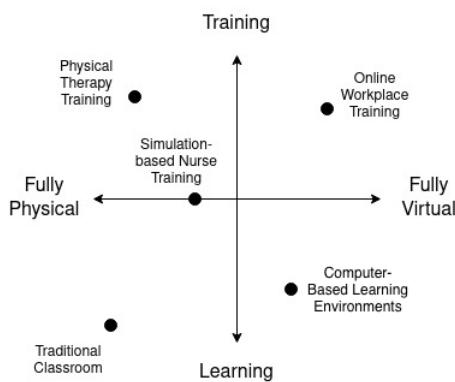

Fig. 2. Learning-Training Continuum

A key distinction between domains lies in their level of structure: **structured** domains (e.g., STEM+C) are characterized by constrained problems and clear evaluation metrics. In contrast, **unstructured** domains (e.g., humanities) involve open-ended tasks with subjective or variable outcomes. For instance, algebra problems typically follow well-defined procedures. They can be assessed using rule-based systems such as decision trees [189], whereas creative writing tasks [210] resist formulaic evaluation and are often poorly served by metrics like word count or sentence length [77]. However, with the advent of LLMs, analytical rubrics are being developed that break down writing into specific criteria, such as uniqueness of storyline, logical sequencing of ideas and content (e.g., a connected beginning, middle, and end of the narrative), style of writing, and engaging vocabulary [80, 99].

Structural differences affect how multimodal learning environments are designed and how data are captured and analyzed. Structured domains often afford quantitative, model-based analysis, while unstructured domains typically require model-free, qualitative methods such as thematic or interaction coding [90]. However, the line between the two is becoming increasingly blurred with the integration of LLMs, which can interpret and evaluate multimodal data even in unstructured, dynamic contexts such as embodied learning.

Participant Interaction Structure. Participant interaction structure describes whether learners engage individually (**individual**) or with others (**multi-learner**). Individual settings typically involve a single learner interacting with systems such as educational games [103], intelligent tutoring systems [26], open-ended learning environments [106], and creative platforms [54]. Multi-learner environments include pairs, small groups, or full-class activities such as paired programming [159], game-based competitions [155], and collaborative play [11].

Our corpus reveals a growing emphasis on collaborative learning, with multi-learner studies increasing from 42% (31/73) in Corpus A [64, 146] to 51% (25/49) in Corpus B [148, 204]. These studies leverage multimodal data to examine activities such as collaborative experimentation [63], clinical simulations [213], and group reflections using dashboards [65, 71]. In contrast, individual-focused studies emphasize personalization [207] and self-regulation, often through AI-driven tutors [93], gaze-adaptive systems [162], or LLM-integrated dashboards [111].

Multi-learner settings introduce social interaction as a central dimension, enabling insights not possible in individual contexts. Learners often externalize their thinking, allowing researchers to analyze dialogue [213], coordination [108], and socially shared regulation of learning (SSRL) via audio and video [88]. However, such contexts present analytic and logistical challenges, including smaller effective sample sizes (n) [87] and reduced transcription quality due to classroom noise [17].

Didactic Nature of the Environment. Didactic nature refers to how learning or training is presented to participants. **Instruction** involves formal activities with defined objectives (e.g., courses, labs) [22, 50, 89]. **Training** emphasizes skill development through practice (e.g., clinical simulations, vocational drills) [70, 125, 126]. **Informal** settings lack fixed goals and occur in loosely structured contexts (e.g., game-based learning, exploratory play) [37, 66, 149, 201].

Both corpora are dominated by instruction, with an even stronger emphasis in Corpus B (A: 45/73; 62%; B: 40/49; 82%). For example, Liu et al. [114] analyzed student interactions in a chemistry virtual lab, integrating logs with audio and video to uncover learning difficulties not evident from system data alone. Training environments accounted for 20-25% of both corpora (A: 15/73; 21%; B: 11/49; 23%), such as a simulated social skills trainer for youth with autism using audiovisual cues like head pose and smiling ratio. Informal learning settings declined notably from Corpus A to B (A: 12/73; 16%; B: 1/49; 2%), as LLMs were primarily applied in traditional instructional contexts. For instance, Santhosh et al. [162] combined real-time gaze-based engagement detection with ChatGPT-generated summaries to support reading comprehension while studying.

838 Training prioritizes repetition and performance [126], while instructional and informal settings differ in design,
839 data, and analysis. Instructional tasks are structured, allowing controlled data capture and model-based analysis [211].
840 Informal settings are open-ended, generating noisy, varied, and often incomplete data requiring qualitative, model-
841 free, and human-in-the-loop decision-making approaches [6, 177]. Goals also vary: instruction targets conceptual
842 understanding [94], while informal learning fosters creativity, exploration, and inquiry [62].
843

844 *Level of Instruction or Training.* Our framework defines three levels of instruction: (1) **K–12** (primary and secondary
845 education) [67, 89, 146], (2) **University** (undergraduate and graduate) [50, 131, 134], and (3) **Professional Development**
846 (e.g., workplace learning, continuing education) [54, 60, 155].
847

848 Both corpora show similar trends across instructional level, skewed heavily toward university learners (A: 36/73;
849 49%; B: 29/49; 59%). For example, Civit et al. [36] demonstrates that ChatGPT’s classroom integration, paired with
850 physiological signals (e.g., galvanic skin response) supports emotional state detection and structured AI-tutoring
851 interventions with college students, improving both engagement and learning outcomes. K–12 settings followed (A:
852 30/73; 41%; B: 19/49; 39%), while professional development was least represented (A: 5/73; 7%; B: 2/49; 4%).
853

854 K–12 and adult learning contexts pose distinct challenges. Research in K–12 settings faces significant ethical and
855 logistical constraints due to the involvement of minors. Multimodal data capture, especially video and physiological
856 sensing, raises privacy and health data concerns, often requiring approval from parents, teachers, administrators,
857 and district officials [45]. The emergence of GenAI raises additional concerns, including student misuse [130] and
858 unintended LLM behaviors [92], making school-based research difficult and often requiring on-site presence.
859

860 In contrast, adult learning environments offer greater flexibility, with fewer institutional hurdles and support for
861 both in-person and remote studies. Despite the formative importance of K–12 education—where students acquire
862 foundational knowledge, social skills, problem-solving strategies, and good study habits [19, 68]—the dominance of
863 university-focused research is unsurprising. Expanding the reach of multimodal systems in K–12 contexts will require
864 coordinated efforts from educators, researchers, parents, and policymakers to ensure these technologies are deployed
865 ethically and effectively [171].
866

867 *C.1.2 Setting.* Settings describe where and how multimodal learning and training activities unfold. Whether learners
868 are on virtual platforms, in physical classrooms, in clinical simulations, or in play spaces constrains which traces can be
869 captured and how analytics and AI-based tools can be meaningfully embedded. Setting links sensing choices, models,
870 and interpretations to the realities of computer-based, in-person, and blended scenarios, and clarifies how multimodal
871 learning analytics systems are deployed across different contexts. With both corpora, we characterize setting along two
872 dimensions: (1) **environment function** and (2) **environment interaction setting**.
873

874 *Environment Function.* We distinguish environments by their primary function, in line with this review’s dual focus
875 on **learning** [50, 51, 91] and **training** [60, 64, 71] contexts. Some research examines both (e.g., language learning and
876 woodworking in the same study [29]). Learning environments dominate both corpora (A: 57/73; 78% [50, 66, 91]; B:
877 40/49; 82% [147, 148]), with training making up a smaller portion (A: 16/73; 22%; B: 12/49; 24% [71, 125]).
878

879 A key distinction between environments is the level of physical engagement: **active** versus **stationary**. Although
880 exceptions exist—such as embodied learning contexts where students move around the classroom and stationary
881 training tasks like oral presentations [144]—most learning environments involve seated participants interacting with a
882 computer, classroom teacher, or each other. In contrast, training typically entails physical activity, such as movements
883 and interactions with objects, to accomplish a task. This distinction, in turn, shapes both data capture and analysis. In
884

active environments, motion capture, video, and physiological sensors generate complex, high-dimensional data that generally require model-based methods (e.g., deep learning). For example, Vatral et al. [193] employed gradient-boosted regression trees on eye-gaze and speech features to predict nursing trainees' self-efficacy. Extending this multimodal approach, Martinez-Maldonado et al. [125] integrated smartwatches, microphones, and positioning sensors. However, the authors noted the need for standardized, researcher-provided devices to ensure data quality—highlighting current limitations of “bring-your-own-device” strategies for scalable deployment.

Environment Interaction Setting. **Virtual** environments occur entirely online or in simulated spaces without physical co-presence [111, 180, 185]. **Physical** environments involve in-person activity in real-world spaces such as classrooms, labs, training facilities, and clinics [28, 178, 200]. **Blended** settings combine both, as in robotics courses where students program physical robots using online interfaces [104]. A shift is evident across corpora: virtual environments dominated Corpus A (51/73; 70%) [7, 180, 185], while Corpus B was led by physical settings (34/49; 69%) [208, 213], reflecting the post-COVID return to in-person learning.

Virtual environments are easier to scale and monitor, primarily because students tend to focus on their computer screens, which limits their movement and enables streamlined data collection through computer-based logs, screen recordings, and webcam feeds [175]. For example, researchers have combined heart rate data from Fitbits with system logs to investigate PhD students' self-regulated learning [61]. These conditions facilitate large-scale, quantitative, and model-based analyses.

However, virtual learning lacks the authenticity of physical settings, especially for K-12 education [79, 168]. Studying learners *in situ* (i.e., in their natural environment) offers critical insight into real-world learning processes. It enables access to affordances like social interactions using sensors that are not replicable online. Yet physical environments require on-site researcher presence, heightened IRB oversight, and face logistical barriers to scale [4]. Noise, technical failures, and unstructured dynamics often produce incomplete or messy datasets [55]. Consequently, physical settings frequently rely on model-free methods, such as qualitative coding or statistical correlations between observed behaviors and outcomes [90].

C.1.3 Data Collection Media (“Sensors” in Figure 1). Data collection media determine which aspects of learning and training can be observed, modeled, and ultimately supported. Their selection shapes the granularity of multimodal traces, the feasibility of signal fusion, and the types of constructs that can be inferred (e.g., performance, collaboration, reflection; see the following subsections). Media can also be combined to form multimodal signals. For instance, prosodic and semantic features extracted from audio can be fused with visual cues to predict affect [154]. Across both corpora, we identified a common set of data collection media, summarized in Table 9.

Figures 3 and 4 compare the distribution of data modalities across Corpora A and B. Video and audio data collection were prevalent across both corpora, indicating the richness and usefulness of integrating these modalities in multimodal settings. Audio data can yield prosodic information, such as tone, pitch, pauses, and volume, alongside the semantic meaning of the spoken words, which can be fused with other data streams to derive modalities downstream [27, 169]. Video data can be used to derive visual modalities like activity, gesture, pose, gaze, and affect [18, 141].

In the post-COVID era, multimodal learning and training studies experienced notable shifts. As research moved from virtual to physical settings, the use of participant-produced artifacts increased while reliance on environment log data declined. This transition, along with the rise of LLMs, enabled richer forms of textual feedback not dependent on rule-based systems derived from logs. Surveys and interviews also became more prominent, reflecting a growing emphasis on stakeholder agency in system design and validation rather than purely technological advancement [43, 44].

Medium	Definition
Video	Sequences of image frames captured from a camera source [37, 67, 153].
Audio	Audio signals captured by a microphone [150, 151, 185].
Screen Recording (Screen)	Sequences of image frames displaying a device's screen contents [5, 91, 114].
Eye Logs	Eye movement data and gaze points captured by tracking devices [26, 149, 186].
Physiological Sensors (Physical)	Participant's actions within the system and its state data [13, 157, 178].
Interview	Specialized sensors used to gather participants' physiological data [84, 95, 115].
Survey	Structured or unstructured conversations between researchers and participants [16, 126, 142].
Participant-Produced Artifacts (PPA)	Standardized sets of questions administered to participants [50, 56, 152].
Researcher-Produced Artifacts (RPA)	Materials produced by study participants using various mediums, including physical objects created for a task or written responses to formative assessment questions [10, 25, 144].
Motion	Materials produced by the researchers that contribute to analysis and findings, such as observational notes [84, 124, 181].
Text	Raw motion data collected via various different devices/technologies [60, 126, 196].

Table 9. Data collection media.

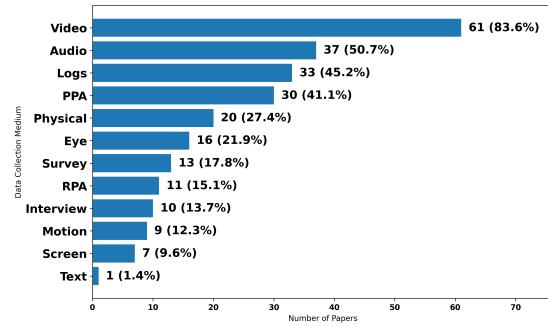

Fig. 3. Corpus A data collection media distribution.

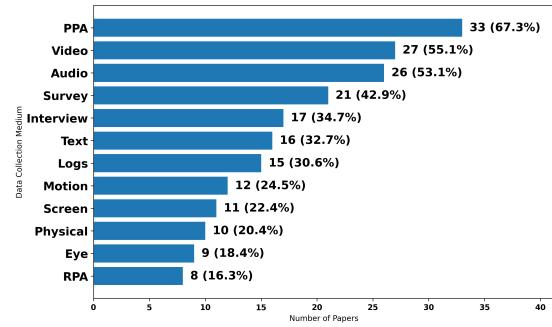

Fig. 4. Corpus B data collection media distribution.

The most striking shift was in textual input: Corpus A included only one study using raw text [201], while nearly one-third of Corpus B papers captured text as a primary data source [54, 109, 111, 134, 202]—almost entirely due to LLM-mediated interactions.

Research goals, target modalities, and participant interaction structures shape data collection methods. For example, studying socially shared regulation of learning requires both environment log data to capture cognitive activity and discourse data to analyze metacognitive and social processes [47, 174, 175]. In contrast, CPR tutor training relies

on motion data and physiological signals (e.g., EMG, accelerometers, gyroscopes) to evaluate chest compression performance [60].

However, some modalities pose challenges to adoption. Video and sensor-based methods raise privacy concerns and are often perceived as invasive [122, 156], while LLM-based systems may raise skepticism due to risks of hallucination, toxicity, and misuse [83, 130]. Self-reported measures, such as interviews and surveys, are valuable but must typically be triangulated with other modalities to ensure reliability [143]. Synchronizing data from multiple data streams is challenging and requires standardization, time alignment, and feature engineering. This process is often time-consuming and requires both domain knowledge and technical expertise, creating additional barriers to adoption.

C.2 Multimodal Data

Multimodal data form the foundation of MMLA systems: choices about what to capture, how to represent it, and which streams to combine determine the learner states and processes that can be modeled, the inferences that can be made about their behaviors and performance, and how analytics can inform action. In our framework, multimodal data sit at the intersection of learner behavior and analytics, linking observable activity across multiple modalities to higher-level constructs (e.g., collaboration quality, regulation of self- and group-learning, knowledge and skill acquisition) [96].

These modality choices shape both traditional MMLA pipelines and GenAI-enabled systems by defining system architecture that determines interpretability, robustness, and analytic scope. We adopt a unified taxonomy of five **modality groups**, which partitions modalities based on how they are derived and the information they convey: (1) natural language, (2) vision, (3) physiological signals, (4) human-centered evidence, and (5) logs. Table 10 presents each modality alongside its corresponding modality group(s), setting the stage for the subsequent sections that examine the constructs and analytic methods enabled by each category.

Figures 5 and 6 show the modality distributions for Corpora A and B, largely reflecting trends in data collection media. Prior to the development of LLMs, COVID-era studies (Corpus A) focused on individual modalities such as pose, logs, affect, gaze, and prosodic speech. These modalities were often collected in virtual settings using tools like microphones, webcams, and trace data.

In contrast, Corpus B reflects a shift toward in-person, multi-party, human-centered studies integrating LLMs and sensor-rich physical environments. This newer corpus emphasizes participant-produced artifacts, transcribed speech, physical activity, surveys, and raw textual inputs, captured through 3-D video, lapel microphones, and student-created materials. Several modalities present in Corpus A—such as prosodic speech, spectrogram, EMG, and blood pressure—are notably absent in Corpus B, underscoring a broader shift from physiological signal-based approaches toward artifact- and LLM-centric methods. Importantly, many post-LLM systems employ large language models not as end-to-end multimodal architectures, but as analytic or interpretive layers operating on representations extracted from other modalities.

Approximately two-thirds of papers in both corpora use 3–5 distinct modalities to guide their research (A: 49/73 [5, 57]; 67%, B: 34/49 [30, 134]; 69%). This reflects a methodological balance: the number is sufficient to enable triangulated inferences across heterogeneous signals (e.g., aligning logs with gaze, or artifacts with surveys), while remaining tractable in terms of data collection, synchronization, and model complexity. This norm becomes especially relevant when incorporating more sophisticated analytic systems, such as LLM-based agents, which must operate within practical limits on data richness and annotation effort. The following subsections detail how the modalities within each modality group are operationalized in practice.

1046 1047	Modality	Description	Modality Group
1048	Affect	Participant's facial expression, or emotional or affective state [57, 157, 185].	NLP, Vision, Physical
1049	Pose	Participant's physical position, location, or body posture [5, 179, 182].	Vision, Physical
1050	Gesture	Participant's gestures and body language [7, 151, 200].	Vision
1051	Activity	Participant's observable actions or activities [76, 114, 155].	Vision, Physical
1052	Prosodic Speech (Pros. Speech)	Elements of speech beyond word meaning, e.g. volume, pauses, and intonation [140, 178, 180].	NLP
1053	Transcribed Speech (Trans. Speech)	Textual speech transcribed from audio [16, 50, 113].	NLP
1054	Qualitative Observations (Qual. Obs.)	Researcher observations about the participant and study task [95, 123, 199].	Human-centered
1055	Logs	Participant's environment actions and system state data [13, 78, 131].	Logs
1056	Gaze	Participant's eye gaze, e.g., movement, direction and focus [66, 67, 206].	Vision, Physical
1057	Interview	Notes from interviews between researchers and participants [12, 64, 91].	Human-centered
1058	Survey	Participant's responses to surveys/questionnaires [149, 150, 152].	Human-centered
1059	Pulse	The participant's pulse, indicating their heart rate [102, 103, 192].	Physical
1060	EDA	Participant's electrodermal activity [101, 121, 170].	Physical
1061	Temperature (Temp.)	Participant's body temperature [105, 149, 170].	Physical
1062	Blood Pressure (BP)	Participant's blood pressure [103, 149, 192].	Physical
1063	EEG	Participant's electroencephalography activity [78, 149, 170].	Physical
1064	Fatigue	The level of fatigue experienced during the activity [102, 103].	Vision, Physical
1065	EMG	Participant's electromyography activity [58, 60].	Physical
1066	Participant Produced Artifacts (PPA)	Artifacts produced by the participant during the study, e.g., pre/post-tests [26, 133, 144].	Human-centered
1067	Researcher Produced Artifacts (RPA)	Artifacts produced by the researcher about the study and participants, e.g., field notes [37, 70, 142].	Human-centered
1068	Spectrogram (Spect.)	Representation of audio frequencies in the form of a spectrogram [119].	NLP
1069	Text	Participant's raw text data generated in the study environment [201].	NLP
1070	Pixel	RGB pixel values from cameras or sensors [155].	Vision

Table 10. Modalities, their definitions, and the modality groups they fall into (detailed in Section C.2).

C.2.1 *Natural Language.* Natural language captures how learners and trainees speak, write, and interact with peers, instructors—and increasingly, LLM-based systems—across modalities such as prosodic and transcribed speech, raw text, and affect derived from language or speech (see Table 10). Because much teaching, collaboration, feedback, and assessment are inherently language-based, NLP signals often encode rich information about learners' metacognition (e.g.,

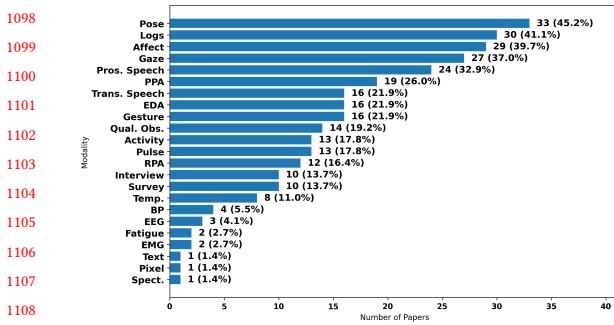

Fig. 5. Corpus A modalities distribution.

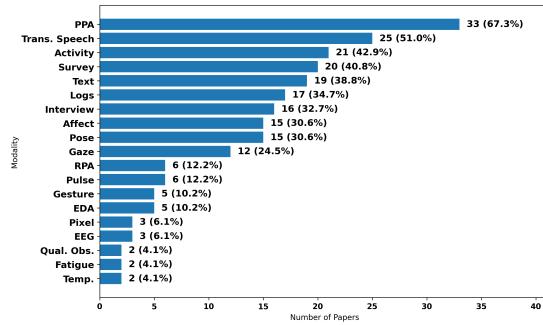

Fig. 6. Corpus B modalities distribution.

goal setting [45], planning [73], and reflective behaviors [175]) as well as collaborative processes such as information pooling and consensus building [176].

Natural language is also frequently used to contextualize other modalities, including gaze, posture, and interaction logs. For example, Snyder et al. [174] employed Markov modeling to infer students' metacognitive states (planning, enacting, monitoring, and reflecting) during collaborative problem solving by integrating environment log data and collaborative discourse, enabling ChatGPT-generated summaries of collaboration to be grounded in students' actions within the learning environment. Zhou et al. [215] used video and conversation data to automatically detect gaze, nonverbal speech, and resource-management behaviors during group learning. Analysis revealed distinctive interaction patterns, including loops between gaze-linked referring/following and resource-management behaviors. These patterns differentiated groups based on their shared understanding and collaborative learning outcomes.

The use of NLP has skyrocketed in recent years, increasing from 35/73 papers (48%) in Corpus A—where prosodic speech was the primary NLP modality—to 40/49 (82%) in Corpus B [107, 112]—where text and transcribed speech were the primary modalities. This shift is closely tied to studies that deploy LLM-enabled systems, such as GPT-based learning aids [112], GenAI-supported multimodal composing [172], and multimodal LLMs for assessment [138]. Natural language features such as raw text, word embeddings, term frequency, loudness, and pitch are consistently reported as informative, with strong associations with predictive outcomes such as learner productivity, performance, and collaborative confusion or conflict. Collaborative settings, in particular, highlight these features as frequently among the most predictive, especially when combined with other multimodal signals [44].

While NLP outputs across Corpora A and B are broadly similar, their methodological approaches differ substantially. Corpus A predominantly uses traditional machine learning techniques such as SVMs [119, 151, 179] and logistic regression [56, 113, 150], often supplemented by qualitative methods (e.g., transcript coding, case studies) to interpret learner discourse and interaction [64, 123, 145]. In contrast, Corpus B centers on LLM-enabled pipelines, particularly for analyzing dialogue and delivering feedback [54, 138, 202]. These systems enable free-flowing conversations that were not feasible prior to the LLM era. In some cases, multimodal LLMs are also used for assessment [138]. Here, LLMs and GenAI tools serve dual roles: they act as interactive components within the learning environment and as generators of textual data for downstream multimodal analysis, with other modality groups (e.g., vision, logs, physiological signals) offering contextual signals around these language-based interactions.

The natural language challenges faced by MMLA researchers also differ considerably between corpora. Corpus A, with its reliance on traditional machine learning, frequently cites issues such as small, imbalanced datasets [38, 40, 41],

1150 113, 114, 150], which hinder the training and adaptation of deep learning and transformer models [12, 39, 42, 150, 181].
1151 The corpus's emphasis on audio data introduces additional challenges, particularly the time-intensive nature of feature
1152 extraction. Tools such as NLTK [117], openSMILE [69], and TAACO [52, 53] can aid this process, but often yield large
1153 and difficult-to-interpret feature spaces [155], while manual preprocessing and feature engineering further constrain
1154 scalability [100, 113]. Conversational agents are rare in Corpus A; when used, they typically deliver static messages or
1155 summative feedback rather than engaging in multi-turn interaction [56, 114, 185]. While using raw text with LLMs (like
1156 in Corpus B) mitigates many of these issues, others arise such as transcription errors from automatic speech recognition
1157 (ASR) in noisy classrooms [100, 178, 201] and concerns surrounding LLMs like adverse interactions with students and
1158 how to effectively evaluate LLM output [24, 92].
1159

1160
1161 C.2.2 *Vision.* Vision-based modalities offer continuous insight into how learners move, attend, react, and interact in
1162 learning and training environments. Cameras and eye trackers capture signals such as affect, pose, gesture, activity, gaze,
1163 and fatigue², which are often inaccessible through logs or language alone. These visual signals are critical for modeling
1164 non-verbal behavior and engagement. In MMLA, they support both model-based approaches (e.g., convolutional neural
1165 networks [179]) and qualitative methods (e.g., interaction analysis [172]), and are frequently triangulated with other
1166 modalities such as logs and speech [172].
1167

1168 The rise of multimodal LLMs such as GPT [1] and Gemini [188] has broadened the role of vision-language models
1169 (VLMs) in MMLA, shifting their use from traditional tasks like classification and coding to more complex applications
1170 in interpretation and sense-making. For example, Yan et al. [205] use GPT-4V to interpret screenshots of nursing
1171 students' learning analytics dashboards, enabling the system to "see" and reason about visual elements such as charts
1172 and graphs. This visual understanding is integrated with retrieval-augmented generation (RAG), enabling the chatbot
1173 to produce explanations grounded in both the dashboard's visual structure and its educational data context. Unlike
1174 traditional machine learning pipelines, VLM-based multimodal integration requires minimal feature engineering. While
1175 neural networks often require pixel data to be normalized or transformed into visual embeddings aligned with textual
1176 representations [85], VLMs can directly accept raw text and image inputs from the user.
1177

1178 There has been a marked shift away from vision modalities in recent years. Whereas three of Corpus A's top four
1179 modalities were vision-based (pose [180], affect [123], and gaze [145]), none appears among the top seven in Corpus B.
1180 Except for the activity modality, the percentage of papers using each vision modality declined³ (see Figures 5 and 6).
1181 Overall, vision-focused papers fell from 59/73 (81%) in Corpus A to 27/49 (55%) in Corpus B. We hypothesize that the
1182 rise in activity papers (A: 13/73; 18% [64, 102], B: 21/49; 43% [8, 172]) reflects a return to in-person research after COVID.
1183

1184 Vision modality group implementations were broadly consistent across corpora, favoring quantitative, model-
1185 based analyses to classify attributes such as pose [109, 178], gaze [180, 202], and affect [152, 162]. These modalities
1186 were typically used in traditional machine learning or shallow deep learning pipelines to infer learner states such as
1187 engagement, collaboration quality, or skill level, often supplemented by qualitative interpretation of predicted classes
1188 [161, 203]. Vision data functioned both as features (e.g., using gaze to predict engagement [208]) and as prediction
1189 targets (e.g., deriving affect from image data [161]). In Corpus B, vision was often one component of larger multimodal
1190 pipelines involving sensors and logs [104], providing contextual grounding for downstream analytics or dashboards [46].
1191 While LLM usage increased overall, vision integration with multimodal LLMs was rare; instead, vision inputs like gaze
1192 were used to inform or condition LLM-based interactions (e.g., as context for ChatGPT [162]).
1193

1194 ²We define **pixel** data in Table 10, but omit further discussion due to its limited use across both corpora.
1195

1196 ³We ignore the fatigue modality due to underrepresentation: one paper in Corpus A and two in Corpus B.
1197

As with natural language, vision-based modalities often contributed significant predictive power to multimodal pipelines. For instance, Acosta et al. [2] demonstrated that integrating trace log data with vision features such as facial action units, head pose, and gaze—extracted using OpenFace [15]—led to more accurate predictions of collaborative satisfaction than any individual modality or subset. Student survey responses served as ground truth, and two specific facial action units emerged as the most predictive features across both high- and low-performing modality combinations. Similarly, Ma et al. [119] used early fusion to combine video features (e.g., facial expressions, body movements, inter-learner distance), linguistic features (text embeddings), and audio signals (e.g., speaking time, pitch) to predict *impasse*, i.e., moments of stalled progress during collaborative problem solving due to conflicting ideas. Their results highlighted facial muscle movements as particularly strong predictors of impasse, underscoring the importance of visual signals in capturing nuanced social dynamics.

However, vision-based multimodal analytics face several practical and methodological challenges. Many learning and training environments lack controlled lighting, fixed camera setups, or specialized hardware (e.g., eye trackers), limiting the feasibility of fine-grained gaze or pose analysis [9, 49, 198]. Additionally, small and noisy datasets often lead researchers to rely on pre-extracted features rather than raw pixel data, which can obscure model assumptions and reduce adaptability across tasks or domains. For instance, commercial tools like iMotions provide real-time emotion tracking from facial muscle movements. Yet, the inferred states (e.g., joy, anger, fear) are typically assumed as ground truth without independent validation. Synchronizing and fusing visual data with other modalities, such as natural language, logs, or physiological signals, remains complex and time-consuming, with missing data and differing temporal resolutions further complicating joint modeling. Additionally, there is growing concern that opaque vision components may introduce bias or misinterpret learner behaviors, particularly for underrepresented populations or non-standard learning contexts [9].

C.2.3 Physiological Signals. Physiological signal-based modalities capture learners' physiological and motion-related traces, including affect, pose, activity, gaze, pulse, electrodermal activity (EDA), body temperature, blood pressure, electroencephalography (EEG), fatigue, and electromyography (EMG). These modalities link learners' observable actions with their internal states, enabling the interpretation of engagement, cognitive load, stress levels, and coordination in both learning and training contexts. Unlike vision-based data, physiological signal modalities are typically used as primary features in predictive models rather than as target outputs.

Physiological signal modalities appear more frequently in Corpus B (23/49; 47% [23, 93]) than Corpus A (A: 20/73; 27% [57, 101]), with notable differences in how they are deployed. In Corpus A, physiological signals are primarily tied to the EDA modality (16/20; 80% [78, 200]), and are disproportionately used in training contexts. Although training constitutes 22% (16/73) of Corpus A studies, it accounts for 40% of those using physiological signals (8/20) [57, 124]). In contrast, physiological signal use in Corpus B shifts toward motion-oriented modalities like activity and pose—each of which appears in 12/23 (52%) of physiological signal-enabled studies [104, 125].

In practice, this leads to different methodological approaches across the corpora. In Corpus A, physiological signals are commonly used for predictive modeling and to examine their relationships with learning behaviors and outcomes. Signal processing converts raw data streams (such as EDA, pulse, and accelerometer readings) into interpretable metrics, including learning gains, team dynamics, and shared arousal. These physiological signals support offline analyses, such as identifying patterns associated with performance, and in-time feedback during training, enabling timely interventions. Additionally, these features are often integrated with other modalities (such as visual data, logs, and language) to provide context for engagement, stress, and coordination.

1254 Corpus B emphasizes interaction-rich environments, such as simulations and collaborative tasks, helping to capture
1255 arousal and cognitive load during the learning process. While the methods employed may vary, the physiological signals
1256 in Corpus B more clearly bridge the gap between “*vision-like*” behavioral traces that focus on students’ observable
1257 actions and their cognitive and emotional states, thereby reinforcing their integrative role in connecting what learners
1258 are doing, how they move, and how their bodies respond [137].

1259 The wide range of modalities derived from physiological and motion-based sensors has yielded diverse and insightful
1260 findings across multimodal learning and training pipelines. For example, Que et al. [158] combined gaze data from
1261 EyeLink 1000 Plus eye trackers with heart rate, inter-beat intervals, and electrodermal activity from an Empatica E4
1262 wristband to predict three types of cognitive load during an English as a Second Language (ESL) reading task: *extraneous*
1263 *load* (avoiding irrelevant information while learning), *intrinsic load* (reflecting the complexity of learning material), and
1264 *germane load* (resources available for processing intrinsic load, e.g., comprehension). They found that extraneous load
1265 was predicted by increased fixation count and lower mean heart rate; intrinsic load by increased fixation count and
1266 mean saccade amplitude; and germane load by increased fixation count and heart rate variability.

1267 While the above example is illustrative, many other studies demonstrate that physiological signals do not yield
1268 generalizable findings across contexts: different sensors work best in different environments, for different tasks, and
1269 with different populations of learners and trainees. Moreover, integrating and interpreting heterogeneous sensor streams
1270 remains technically challenging, and reliance on specialized hardware, such as eye trackers and wristbands, raises
1271 practical concerns about cost, scalability, and privacy. Teachers and students have also emphasized the importance
1272 of understanding how machine learning models generate predictions [48], highlighting the need for interpretable,
1273 human-centered, explainable AI (XAI) approaches when using physiological signals. Without these, stakeholders may
1274 struggle to trust or act on insights derived from these modalities [160, 164].

1275
1276
1277
1278
1279
1280
1281
1282
1283 *C.2.4 Human-Centered.* Human-centered modalities include qualitative observations [136, 148], interviews [54, 142],
1284 surveys [63, 118], and artifacts produced by participants [28, 144] or researchers [84, 128]. These modalities anchor
1285 multimodal learning and training analytics in the lived experiences of learners and the perspectives of educators and
1286 researchers, offering insights into how participants perceive, interpret, and reflect on tasks—insights that are often
1287 inaccessible through sensor or log-based data streams alone. They are frequently used to complement quantitative
1288 findings with rich detail (e.g., via case studies or error analyses), and are often treated as ground truth in predictive
1289 modeling or for correlating learning behaviors with outcomes. Human-centered data are crucial for validating inferences
1290 from other modalities, improving the interpretability of model outputs for stakeholders, and understanding how
1291 multimodal systems are experienced and perceived in practice.

1292 While both corpora incorporated human-centered data, its prevalence rose sharply from Corpus A to Corpus B (A:
1293 45/73; 61% [66, 159], B: 46/49; 94% [93, 125]), reflecting the community’s growing emphasis on stakeholder agency in the
1294 design and evaluation of intelligent systems. In earlier work, methodological studies in educational AI often lacked input
1295 from teachers, students, or learning scientists [41]. With the emergence of LLMs, however, user-centered approaches,
1296 such as participatory design and co-design [86, 163], have become critical, as trust in GenAI systems hinges on their
1297 perceived safety, effectiveness, and alignment with stakeholder needs [45]. Across both corpora, participant-produced
1298 artifacts were the most frequent human-centered modality, with a stronger emphasis in Corpus B (33/46; 72%) [89, 202]
1299 versus A (19/45; 42%) [13, 101].

1306 Human-centered data are most often used for model-free, qualitative analysis, but it can also be annotated for
 1307 quantitative purposes. One noteworthy approach in multimodal learning and training research is *quantitative ethnogra-*
 1308 *phy* [166], which involves applying qualitative coding to data and then extracting quantitative features for analysis.
 1309 This enables the study of complex human behavior through techniques such as network analysis. For example, Sung
 1310 et al. [183] employed multimodal *epistemic network analysis*⁴ (ENA) [167] during a guided reading study in a college
 1311 biology course to examine how sequences of students' self-regulated learning behaviors differed between mastery and
 1312 non-mastery groups. Think-aloud data was analyzed to identify self-regulation strategies (e.g., monitoring, assessing,
 1313 summarizing), while environment log data was used to differentiate between in-class and out-of-class engagement with
 1314 guided reading questions. Quiz scores served as measures of learning outcomes. In both groups, monitoring-related
 1315 verbalizations frequently co-occurred with other self-regulated learning codes; however, the co-occurring codes differed
 1316 by group: in the mastery group, monitoring was more often paired with domain-specific strategies, whereas in the
 1317 non-mastery group, it was more often paired with domain-general strategies. This discrepancy led the authors to
 1318 conduct follow-up qualitative analyses to better understand the contextual nuances of the students' learning processes.
 1319

1320 The challenges surrounding human-centered modalities stem largely from the inherent subjectivity of qualitative
 1321 data and analysis. Observations, participant-produced artifacts, and self-reported measures (e.g., surveys and interviews)
 1322 can introduce coder bias as well as cultural and linguistic biases [127, 139], which may propagate into downstream
 1323 models and compromise generalizability. Furthermore, the manual processes involved in data collection, coding, and
 1324 interpretation are labor-intensive and difficult to scale. Compounding these challenges is the limited standardization of
 1325 coding schemes across studies, particularly for artifacts, interviews, and observational data, which hinders replication
 1326 and cross-study comparison.

1327 *C.2.5 Logs.* Environment logs capture learners' and trainees' interactions with digital tools, platforms, and learning
 1328 environments. In MMLA, these time-stamped traces (e.g., clicks, navigation, tool use) provide a behavioral record that
 1329 can be aligned with other modalities to infer cognitive strategies, engagement, and progress in problem-solving. While
 1330 modalities like language or vision may reveal what participants are thinking or feeling, log data indicate what they are
 1331 actually doing. These streams are highly integrative, often providing context for interpreting focal modalities such as
 1332 natural language and vision. Log data are used similarly across both corpora in terms of frequency and methodology
 1333 (A: 30/73; 40% [5, 149], B: 17/49; 35% [46, 134]).

1334 Studies often use log data in supervised machine learning contexts, extracting features such as mouse clicks, click
 1335 frequencies, click sequences, and inactivity (i.e., no clicks) as inputs for models like logistic regression, support vector
 1336 machines (SVM), and random forests to predict outcomes like task performance and engagement [76, 121, 206]. Statistical
 1337 analyses are also common, linking log-derived metrics to learning gains and behavioral patterns, for example, by mining
 1338 clickstream sequences to infer cognitive strategies such as constructing, debugging, and assessing [173].

1339 LLMs have broadened the interpretive scope of log data by enabling its direct integration into prompts as contextualized
 1340 natural language. For example, Fonteles et al. [74] used late fusion in an embodied learning setting: gaze, speech,
 1341 and log data were first classified with unimodal deep learning models, then combined as text-based input to an LLM to
 1342 interpret students' socially shared regulation. Similarly, Cohn et al. [44] translated students' block-based programming
 1343 actions into natural language to contextualize collaborative discourse during RAG with an LLM-based pedagogical
 1344 agent. Incorporating log data to situate discourse within the learning environment improved semantic alignment and

1345 ⁴ENA transforms coded qualitative data into visual networks that reveal how coded concepts co-occur over time. Data segments (e.g., collaborative
 1346 discourse turns) are coded according to a theoretical framework; nodes represent codes, and edges reflect their co-occurrence within a pre-defined
 1347 window. Edge thickness encodes co-occurrence frequency, enabling temporal comparisons across groups and assessment of learning processes.

1358 retrieval performance relative to using discourse alone. Students also reported positive interactions with the agent,
1359 indicating its potential to enhance engagement and support in collaborative learning.
1360

1361 The main drawback of environmental log data is that it is usually only applicable in digital settings, such as virtual
1362 or blended environments, but not in fully physical ones. Time alignment and temporal granularity present challenges
1363 for multimodal fusion. Researchers often need to reconcile different sampling rates, synchronize events across various
1364 modalities, and manage high-dimensional time series. Additionally, log-based models frequently struggle to generalize
1365 across different systems, partly due to the limited adoption of interoperability standards, such as xAPI and LMS-based⁵
1366 logging. The engineering costs can also be quite high, as building robust logging infrastructures and analysis pipelines
1367 demands significant software development effort, which can impede both reuse and scalability.
1368

1370 C.3 Learning Analytics

1371 Learning analytics involves transforming data into actionable insights to better understand how students learn and train.
1372 This module connects the diverse data streams generated during learning and training activities with the inferences
1373 researchers draw to understand learner behavior and deliver more effective feedback. It consists of two main components:
1374 **data fusion**, which focuses on integrating diverse data streams, and **analysis**, which centers on interpreting this data.
1375 In the following subsections, we will explore both components in detail.
1376

1377 *C.3.1 Data Fusion.* Data fusion is essential for leveraging multiple data sources to enhance our understanding of
1378 learning and training. Only through fusion can we construct unified representations of learners and trainees that
1379 surpass the explanatory power of unimodal approaches. Just as humans rely on multiple senses to understand the world,
1380 data fusion allows researchers to integrate diverse modalities to better capture the conditions under which learners
1381 struggle, improve, and progress.

1382 The conventional classification of fusion methods in MMLA, as defined by Chango et al. [27], includes three types:
1383 *early*, *late*, and *hybrid* fusion. Early (feature-level) fusion merges raw data from different sources at the initial processing
1384 stage. While it captures inter-modal interactions effectively, it faces challenges related to data heterogeneity and model
1385 complexity. Late (decision-level) fusion processes each modality independently before integrating results, enabling
1386 modality-specific insights but often overlooking inter-modal dynamics. Hybrid fusion blends these approaches, fusing
1387 data at multiple stages to exploit both inter-modal synergies and unimodal depth. However, this increases pipeline
1388 complexity and requires careful feature selection and synchronization.
1389

1390 We argue that this three-way classification does not adequately reflect the complexity of modern multimodal analysis.
1391 Our review revealed difficulties in categorizing fusion practices due to inconsistencies in defining “*raw*” versus “*processed*”
1392 features. For example, skeletal joint position data from a Microsoft Kinect may be considered raw by some since it is
1393 directly available from the device, but processed by others, since it is computed internally by the Kinect system from
1394 raw depth data.
1395

1396 To resolve such ambiguity, we adopt and formalize the notion of *mid fusion*, drawing from the concept of the
1397 *observability line* proposed by Di Mitri et al. [59] that separates the *input space* (i.e., observable evidence) from
1398 the *hypothesis space* (i.e., inferred constructs). While the authors note that the boundary between observable and
1399 unobservable features is conceptual and context-dependent, we use this distinction to define four fusion categories that
1400 are summarized in Table 11 and illustrated in Figure 7.

1409

Category	Description
Early Fusion	Draws inferences and computes analytics from multiple sources of raw, directly observable data at the earliest stage of processing before any modality-specific analysis [101, 184, 200].
Mid Fusion	Represents a compromise that mixes early and late fusion for analysis by combining processed, observable features generated from individual sources with analysis using other sources of data within the input space [56, 66, 67].
Late Fusion	Analysis is performed on individual modalities, and the inferences (abstracted and unobservable) are combined to generate outcomes at a later stage, i.e., in the hypothesis space [145, 153, 157].
Hybrid Fusion	Combines the strengths of both early and late fusion methods. Data from various sources are combined at multiple stages of processing [5, 7, 155].
Other	Studies that do not fit into the early, mid, late, or hybrid categories, or where the fusion point was not specified, fusion was not performed, or fusion was performed qualitatively through observation [91, 95, 123].

Table 11. Data fusion approaches.

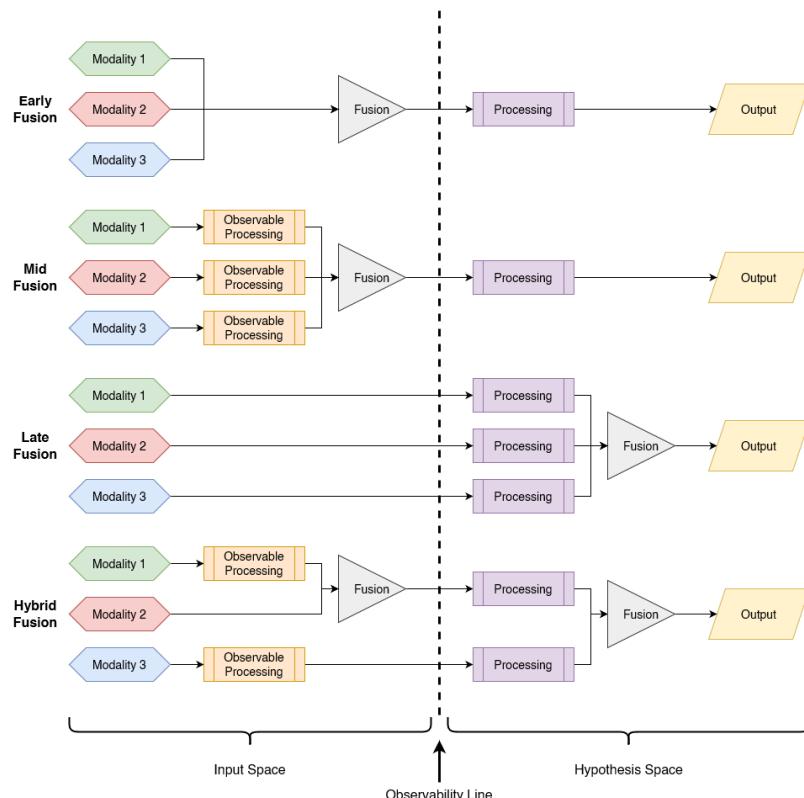

Fig. 7. Multimodal data fusion scheme according to when fusion is performed relative to the observability line.

1462 For instance, Kinect raw pixel or depth data fit early fusion; skeletal joint position data—processed but still observable—
1463 fit mid fusion. We do not consider standard feature engineering practices, such as normalization, standardization,
1464 binning, or one-hot encoding, as constituting “processed” data for the purposes of our taxonomy. Data subjected only to
1465 these transformations would still fall under early fusion, and inferred constructs that are not observable, like planning
1466 and motivation, align with late fusion. Although the boundary between categories remains flexible, introducing mid
1467 fusion helps clarify methodological ambiguity and highlights distinctions among MMLA sub-communities in terms of
1468 their fusion practices.
1469

1470 Fusion strategies demonstrated a notable consistency across both corpora, with mid fusion being the most commonly
1471 used approach. In Corpus A, 27 out of 73 papers (37%) utilized mid fusion [76, 192], while in Corpus B, 19 out of 49
1472 papers (39%) followed suit [65, 108]. This indicates a tendency to process features before integrating modalities. Hybrid
1473 fusion was also present in both corpora, though it appeared less frequently in Corpus B (Corpus A: 19/73; 26% [31, 206];
1474 Corpus B: 8/49; 16% [11, 128]). In contrast, standalone instances of early or late fusion—outside of hybrid contexts—were
1475 rare in both datasets. It is important to note that a significant portion of the papers either did not perform fusion, did
1476 not disclose their fusion methodology, or employed alternative non-canonical strategies (e.g., “qualitative” fusion, which
1477 involves considering multiple modalities simultaneously during qualitative analysis). These instances accounted for
1478 27% of papers in Corpus A (20/73), and 31% in Corpus B (15/49) [124, 186].
1479

1480 The ways in which fusion was implemented varied widely across studies. Mid fusion was particularly common in
1481 settings that used devices such as the Microsoft Kinect. Hybrid pipelines were often preferred in studies that incorporated
1482 three or more modalities, likely because of their flexibility in handling complex, heterogeneous data. No discernible
1483 pattern emerged between fusion type and the nature of input or output variables: both mid and hybrid fusion approaches
1484 were used to combine input features such as discourse embeddings, prosody, affect, behavior traces from physiological
1485 sensors, and log data. These combinations were frequently used to predict collaboration and learning quality, or to
1486 support students and teachers through real-time feedback and multimodal dashboards [29, 72, 132].
1487

1488 While less common, fusion with multimodal LLMs was explored in Corpus B to enable end-to-end interpretation of
1489 complex, multimodal artifacts. For example, Whitehead et al. [197] used GPT-4o to annotate students’ posture during
1490 collaborative physics tasks by fusing cropped video frames with expert-defined textual prompts and a coding scheme.
1491 Fusion occurred at inference time within the model, which produced categorical posture annotations (e.g., sitting,
1492 leaning) as tabular outputs for downstream analysis. Results showed high test-retest reliability and strong agreement
1493 with human raters for simpler behaviors, though accuracy declined for more context-dependent postures. Additionally,
1494 the authors noted that performance in this context is heavily reliant on data quality, “careful prompt engineering,” and
1495 human validation.
1496

1497 Several non-LLM challenges related to fusion emerge as well—perhaps none more significant than the alignment,
1498 integration, and deployment of heterogeneous data sources in real-world settings (i.e., cross-modal interaction). These
1499 challenges include reconciling disparate sampling rates, addressing inconsistent data quality, and managing missing
1500 values, all of which complicate synchronization and modeling. Fusion pipelines often demand extensive preprocessing,
1501 manual calibration, and domain expertise to ensure that signals are both temporally aligned and semantically coherent—
1502 requirements that are especially difficult to fulfill in real-time or online learning environments. Consequently, despite
1503 methodological advancements, the practical barriers to achieving robust, generalizable fusion remain a central bottleneck
1504 for MMLA research and its broader implementation.
1505

C.3.2 Analysis. Analysis is how researchers transform multimodal traces into evidence about learning and training. The research questions determine which forms of analysis are appropriate (e.g., supervised vs. unsupervised, qualitative vs. quantitative, temporal vs. static), depending on the types of insights researchers hope to gain. We classify **analysis approaches** as either **model-based** or **model-free**. Model-based analysis relies on formal models to uncover the underlying structure of the data and the interrelationships between variables. These models often involve mathematical formulations, such as machine learning functions, or computational simulations that encode theoretical assumptions about learning processes. In contrast, model-free approaches avoid such assumptions, instead using empirical statistics (e.g., correlations) or qualitative analyses to identify patterns and relationships directly from the data.

Similarly, we use the term **analysis method** to refer to the specific techniques employed to derive insights from multimodal data in learning and training contexts. These methods, which are summarized in Table 12, range from supervised and unsupervised machine learning (e.g., classification, clustering) to qualitative approaches and network-based analyses. It is important to note that there is no one-to-one mapping between analysis approaches and methods, as both model-based and model-free approaches can employ a variety of methods.

Method	Definition
Classification	Assigning pre-defined labels to input data based on feature analysis through supervised learning (often via deep learning approaches) [5, 157, 180].
Regression	Predicting continuous numerical values through supervised learning to understand input-output relationships [57, 153, 178].
Clustering	Grouping data based on patterns or similarities using unsupervised learning [7, 22, 37].
Qualitative	Manually examining and interpreting data to uncover patterns or themes [91, 95, 123].
Statistical	Using statistical methods (e.g., correlation) to analyze data and draw conclusions [113, 118, 144].
Network analysis	Studying relationships and interactions using graph-based approaches [31, 50, 140].
Pattern Extraction	Identifying meaningful patterns or structures within data, including techniques like Markov analysis and sequence mining [136, 149, 186].

Table 12. Analysis methods.

There is a notable shift from model-based analysis in Corpus A (57/73; 78% [12, 78]) to model-free approaches in Corpus B (33/49; 67% [116, 203]). Model-based analyses in both corpora primarily involve supervised learning methods, such as classification and regression, often supplemented by statistical techniques (e.g., correlation analysis). These studies typically use input features derived from speech, video, log, and sensor data to predict outcome variables such as performance or engagement [5, 157, 178]. They focus primarily on individual learners, reflecting the difficulty of capturing complex social dynamics within formal, parameterized models.

In contrast, model-free approaches take a more exploratory stance, employing qualitative, clustering, statistical, and pattern-extraction techniques. Qualitative methods (e.g., interaction analysis) draw on theory and observation to interpret multimodal traces [123], while statistical and pattern-based approaches highlight relationships between behavior and outcomes (e.g., correlations between strategies and learning gains). These methods are especially prevalent in collaborative learning settings, where they are used to unpack social signals and discourse [50, 140].

For example, Xu et al. [203] used k-means clustering to identify collaborative patterns in undergraduate pair programming using standardized ratings of process quality (9 dimensions) and programming outcomes (4 dimensions). The resulting clusters differed meaningfully in both collaboration quality and performance. High-performing pairs engaged in knowledge construction, consensus-building discourse, positive affect, and iterative loops between talk and code adjustment. In contrast, lower-performing clusters were marked by self-talk, fragmented regulation, excessive debugging, and weaker coordination between discourse and behavior. Clusters were labeled consensus-achieved, argumentation-driven, individual-oriented, and trial-and-error, with the consensus-achieved group showing the strongest outcomes. Here, clustering functioned as a mid-level segmentation step, enabling data-driven insights into how multimodal interactions help explain relationships between collaboration and learning outcomes without relying on prior assumptions.

While both model-based and model-free methods are valuable across both corpora, each comes with inherent trade-offs. A persistent tension exists between the predictive strength and structure offered by model-based approaches—allowing researchers to leverage domain knowledge to define variable relationships that effectively guide analysis—and the interpretive richness and flexibility of model-free analyses that allows for the discovery of unanticipated insights. Choosing between them is not always straightforward. A balanced and often beneficial strategy is to employ both approaches in tandem: model-based analysis to test hypothesized relationships, while model-free methods to reveal latent patterns.

C.4 Feedback

In multimodal learning and training environments, feedback emerges when systems are deployed in real-world contexts (e.g., classrooms), typically taking one of two forms. **Direct feedback** refers to feedback explicitly provided to the user by the system—such as a pedagogical agent assisting a student—to improve performance or other learning metrics. **Indirect feedback**, conversely, is not intended for the end user but is derived from analysis of system use or learner behavior. It informs researchers and developers on how to refine their systems. Such feedback may arise from observing user-system interactions or analyzing outcomes across learner populations, ultimately leading to deeper insights that can be used to improve systems. Both types of feedback are essential for advancing MMLA and helping close the loop between methodological innovation and applied practice.

Every paper in Corpora A and B incorporated indirect feedback in some capacity [120, 179], highlighting the importance of using authentic studies with human subjects to refine system behavior. By contrast, the extent to which direct feedback was employed varied considerably across the two corpora. In the pre-LLM era, only 41 of 73 papers (43.8%) provided direct feedback to users, compared to 30 of 49 papers (61.2%) in the post-ChatGPT era [56, 124]. The LLM era has also enabled significantly more dynamic forms of direct feedback: learners and trainees can now engage in *dialogic* interactions, receiving feedback through rich exchanges with LLM systems that retain conversation history and support stateful interaction [30, 36].

The way multimodality is employed to deliver direct feedback differs substantially across the two corpora. For example, before LLMs, Petukhova et al. [151] introduced the *Virtual Debate Coach*, which monitors trainees' speech, prosody, posture, and gestures through multimodal sensing and analysis. The system extracts features such as filled pauses, speech pitch, and gestures derived from 3-D video coordinates to train an SVM classifier that estimates debaters' confidence levels. Feedback is then generated using predefined rules and expert-informed strategies.

Researchers used indirect feedback in this case to extend the system's machine learning capabilities by enabling automatic detection and interpretation of behavioral variation, as well as assessment of debater proficiency. Direct feedback was provided both formatively and summatively to help students improve their performance and confidence;

1618 however, student-agent interactions are stateless, lacking dialogue-state tracking, turn-level language modeling, or
 1619 access to conversational history. This represents a canonical pre-LLM feedback paradigm in which multimodal features
 1620 are manually engineered and combined with rule-based or heuristic logic to produce feedback within a discrete response
 1621 space.
 1622

1623 By contrast, multimodal LLMs operate in a continuous space and can process heterogeneous data directly, without
 1624 requiring engineered features. Nguyen and Park [138] employed GPT-4o to automatically score and generate explanatory
 1625 feedback on students' multimodal science assessments. The authors demonstrated that LLMs can ingest handwritten
 1626 student assessments—including textual and visual content as a single input—with over 90% transcription accuracy,
 1627 achieving grading alignment comparable to human raters (Cohen's $k = 0.84$). Feedback quality was further enhanced
 1628 through prompt engineering with few-shot exemplars, yielding responses that were more accurate and better aligned
 1629 with teacher feedback.
 1630

1631 While their system provided direct feedback to students in the form of a score and an accompanying explanation,
 1632 they also used indirect feedback to improve system design through thematic error analysis. As the authors themselves
 1633 note, the findings "present opportunities for designing learning analytics systems that allow for iterative evaluation and
 1634 modification [of LLMs'] assessment output" [138]. Their analysis revealed that the LLM (1) failed to evaluate the depth
 1635 of students' responses accurately, (2) hallucinated information not present in the prompt, and (3) exhibited inaccurate
 1636 numerical reasoning. These were identified as the most critical issues to address in future iterations.
 1637

1638 Additionally, the ease of deploying LLM-based feedback systems at scale (e.g., via API calls to OpenAI) has contributed
 1639 to the emergence of multimodal dashboards and tools that serve as feedback layers for teachers and students, supporting
 1640 guided reflection and debriefing rather than functioning solely as research instruments [65, 104]. In parallel, the
 1641 multimodal capabilities of enterprise LLMs such as ChatGPT, Claude, and Gemini have facilitated the integration of
 1642 GenAI-based systems with logs, artifacts, and other multimodal traces to generate personalized, data-driven feedback.
 1643 These systems are designed to support self-directed learning, enhance engagement, and improve learner performance [54,
 1644 109, 111].
 1645

1646 However, the rise of LLM-based feedback systems has introduced several challenges for multimodal learning and
 1647 training. Human feedback often outperforms or qualitatively differs from AI-generated feedback, particularly in complex
 1648 tasks [74]. This gap highlights ongoing design tensions around trust, interpretability, and the roles of human and AI
 1649 actors in direct feedback ecosystems [8, 51].
 1650

1651 In addition, the innate fusion capabilities afforded by contemporary multimodal LLMs often come at the expense of
 1652 user control and transparency. While feature engineering is time-intensive, it enables researchers to evaluate which
 1653 features contribute to model performance. In contrast, LLMs typically accept a single multimodal input [138], internally
 1654 extracting features that are neither observable nor modifiable by users, and whose influence can only be evaluated
 1655 indirectly through techniques such as perturbation analysis.
 1656

1657 Recent work has shown promising results using multimodal late fusion with LLMs for direct feedback by first
 1658 distilling each modality into text and then leveraging the LLM to perform textual fusion [74, 75] before feedback.
 1659 However, this approach relies heavily on prompt engineering. Most studies employ ad hoc prompting strategies, with
 1660 limited attention to systematically aligning generated feedback with established pedagogical principles [45]. This gap is
 1661 often attributed to the absence of established learning frameworks in software engineering pipelines [48].
 1662

1670 C.5 Summary

1671 The four framework components—Environment, Multimodal Data, Learning Analytics, and Feedback—collectively
 1672 illustrate how multimodality is used in learning and training environments. The environment determines which
 1673 modalities can be captured and in what context, setting the stage for meaningful data collection. These interactions
 1674 yield rich multimodal data streams, each offering unique windows into learning and training processes. Learning
 1675 analytics fuses the heterogeneous data for analysis to extract insights, uncover patterns, and make inferences about
 1676 learning and performance. These insights are used to generate feedback, either directly to learners and trainees or
 1677 indirectly to researchers, engineers, and system designers to inform theory and improve educational tools. Across all four
 1678 components, multimodality is the connective tissue that enables holistic, context-aware, and actionable understandings
 1679 of learning and training in complex environments.

1680 However, the approach to multimodal learning and training research differs markedly between Corpus A and
 1681 Corpus B. Table 13 outlines key methodological shifts from pre-LLM multimodal learning analytics to more recent
 1682 GenAI-enabled practices, highlighting how large transformer-based models have redefined data requirements, fusion
 1683 strategies, and analytic workflows. Although researchers in Corpus B continue to apply and refine traditional methods
 1684 established in Corpus A, the rapid adoption of LLMs and GenAI signals a clear and ongoing paradigm shift in the field.

1690 D Literature Review Limitations

1691 This review has three primary limitations: the use of Google Scholar for the literature search, the application of citation
 1692 graph pruning for corpus reduction, and inconsistencies in versioning across published papers. Each is discussed below.

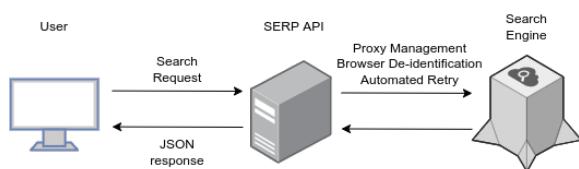

1693 D.1 Google Scholar

1694 Google Scholar, while widely used in academia and industry, presents challenges for reproducibility. Its proprietary
 1695 ranking algorithm is opaque and presumably variable, with results influenced by factors such as user location, search
 1696 history, the time of query, and possible A/B testing. Because the algorithm is constantly evolving and individualized,
 1697 exact reproduction of our search results cannot be guaranteed.

1698 To mitigate this, we used SerpAPI—a web scraping service that queries Google Scholar via randomized headers
 1699 and proxies without user account data (Figure 8). SerpAPI’s documentation confirms that no personal information
 1700 is attached to API requests, and the API supports reproducibility through standardized, non-personalized queries.
 1701 Additionally, SerpAPI recommends validating results using the included search URLs in browser incognito mode.

1702 We also contacted SerpAPI directly, who confirmed: “No, we don’t add any personal information,” and noted that
 1703 others can reproduce results by using the same search parameters. While we agree this may be optimistic given Google’s
 1704 opacity, we are reasonably confident that our initial search was free from personal bias due to the nature of the SerpAPI
 1705 interface. For reference, all searches were conducted in Nashville, TN, USA.

1713 D.2 Citation Graph Pruning

1714 As detailed in Appendix Section B.2.1, we
 1715 used citation graph pruning to programmatically
 1716 reduce our corpus. This approach may
 1717 have excluded some relevant works that had
 1718 few citation connections within the corpus.

1719 Manuscript submitted to ACM

Fig. 8. Searching Google Scholar via SerpAPI.

Dimension	Pre-LLM MMLA Methods (2017–2022)	Post-LLM / GenAI-Enabled MMLA Methods (Late 2022–Present)
Feature Engineering	Predominantly manual and domain-specific feature extraction (e.g., hand-crafted gaze metrics, prosodic features, rule-based textual features).	Reduced reliance on manual feature engineering through pretrained representations and prompt-based abstraction, though handcrafted features remain common in applied settings.
Model Architectures	Classical machine learning (e.g., SVMs, random forests) and task-specific deep learning models (e.g., CNNs, LSTMs).	Increasing use of transformer-based foundation models (e.g., LLMs, VLMs, multimodal transformers—particularly GPT-series models), often combined with task-specific components.
Fusion Strategies	Explicit early, mid, or late fusion pipelines designed and tuned per task.	Hybrid fusion approaches combining explicit fusion pipelines with implicit cross-modal reasoning enabled by pretrained models.
Data Requirements	Substantial labeled datasets are required for model training and validation.	Support for reduced annotation through transfer learning and zero- or few-shot inference, depending on task and context.
Adaptability Across Tasks	Limited generalization; models are typically trained for a single task or environment.	Improved cross-task and cross-domain transferability enabled by pretrained models, though adaptation remains context-dependent in applied environments and can require substantial prompt engineering.
Handling of Unstructured Data	Limited support for open-ended or qualitative data (e.g., discourse, reflection, embodied activity).	Improved capacity to process unstructured and open-ended multimodal data, particularly in language-rich and mixed-modality tasks.
Human-in-the-Loop Interaction	Primarily offline analysis and post-hoc interpretation of multimodal data.	Emerging support for interactive and human-in-the-loop analytics, including AI-assisted feedback and sense-making in certain contexts (e.g., assessment).
Interpretability and Transparency	Relatively interpretable pipelines with explicit features and model logic.	Foundation models introduce new interpretability challenges, alongside emerging practices for prompting, validation, and human oversight.
Scalability and Deployment	Deployment constrained by sensing setups, preprocessing pipelines, and model retraining requirements.	Easier prototyping and deployment via APIs and pretrained models, coupled with new constraints related to cost, latency, privacy, and governance.
Methodological Constraints	Strong dependence on controlled data collection, domain expertise, and context-specific sensing infrastructures.	Shift toward software-centric constraints, including model access, computational cost, data privacy, and alignment with institutional policies.

Table 13. Comparison of Pre-LLM (Corpus A) and Post-LLM (Corpus B) Methodological Affordances in Applied Multimodal Learning and Training Analytics

few citation ties were less likely to represent foundational or widely used methods.

Importantly, even after CGP, over half the remaining papers were ultimately excluded during qualitative screening. This suggests that CGP still retained many irrelevant works, reinforcing our confidence that the method did not omit significant in-scope works.

However, our goal was to identify core contributions in the field—papers that either built upon, or were built upon by, other relevant works. We reasoned that isolated papers with

1774 D.3 Versioning

1775 Many papers in our corpus appeared in multiple forms across preprint servers and publication venues, often with
1776 inconsistent metadata. We used the earliest available public release date when possible. However, discrepancies may
1777 remain, particularly for papers from 2022-2023, where preprint and publication dates may differ by months.

1778 As a result, it is possible that some Corpus B papers were written before the public release of ChatGPT (November
1779 2022). Nonetheless, the sharp rise in publications in 2025 (see Figure 1 in the main manuscript) strongly suggests that
1780 generative AI was the driving force behind these works, which our own analysis reinforces. Any misclassification in
1781 dating is expected to be minor and unlikely to affect our overall findings or conclusions.
